

KES PROTOCOL

Overview

The KES is an application-level protocol created to be used in a specific client-server application that functions as a virtual library. It is stateful, simple and intuitive. KES allows data exchange between a server and multiple clients, embracing all necessary commands to the application functions properly.

After a connection is established between server and client, the last must send a line-command request according to KES rules — followed by its parameters if necessary — and the first will answer with a code informing the status of the response and other parameters if needed.

Request Methods

No login required

REGISTER [username] [password]

Register a new user.

LOGIN [username] [password]

Login to be able to perform other requests.
